# Risk Management & Financial Regulation Final Examination

Thierry Roncalli

January 7<sup>th</sup> 2019

**Please write entirely your answers.** The correction of exercises will be available in the next release of the lecture notes.

#### 1 The BCBS regulation

- 1. What are the main differences between the first Basel Accord and the second Basel Accord?
- 2. Explain how the Basel III Accord strengthens the banking regulation?

### 2 Market risk

- 1. What is the difference between the banking book and the trading book? Define the perimeter of assets for capital requirements.
- 2. How is calculated the capital requirement with the internal model-based approach in Basel II?
- 3. How is calculated the capital requirement with the internal model approach in Basel III (FRTB)?

### 3 Credit risk

- 1. What is the definition of the default in Basel II?
- 2. Describe the standard approach (SA) to compute the capital requirement.
- 3. Define the different parameters of the internal ratings-based (IRB) approach. What are the differences between FIRB and AIRB?

# 4 Counterparty credit risk (CCR) and credit value adjustment (CVA)

- 1. Define the concept of counterparty credit risk. What differences do you make between the CCR capital charge in Basel II and the CVA capital charge in Basel III?
- 2. How is calculated the CCR capital requirement? Explain why the exposure-at-default (EAD) has to be estimated.
- 3. How is calculated the CVA capital requirement?

### 5 Operational risk

- 1. What is the definition of operational risk? Give two examples.
- 2. Describe the standardized approach (TSA) to calculate the capital charge.
- 3. Describe the loss distribution approach (LDA) to calculate the capital charge.

### 6 Market risk of a long/short portfolio

We consider an investment universe, which is composed of two stocks A and B. The current prices of the two stocks are respectively equal to \$50 and \$20. Their volatilities are equal to 25% and 20% whereas the cross-correlation is equal to +12.5%. The portfolio is long of 2 stocks A and short of 5 stocks B.

- 1. Gaussian risk measure
  - (a) Calculate the Gaussian value-at-risk at the 99% confidence level for a ten-day time horizon.
  - (b) Calculate the Gaussian expected shortfall at the 97.5% confidence level for a ten-day time horizon.
- 2. Historical risk measure

The ten worst scenarios of daily stock returns (expressed in %) among the last 250 historical scenarios are the following:

s	1	2	3	4	5	6	7	8	9	10
$R_A$	-0.6	-3.7	-5.8	-4.2	-3.7	0.0	-5.7	-4.3	-1.7	-4.1
$R_B$	5.7	2.3	-0.7	0.6	0.9	4.5	-1.4	0.0	2.3	-0.2
$R_A - R_B$	-6.3	-6.0	-5.1	-4.8	-4.6	-4.5	-4.3	-4.3	-4.0	-3.9

- (a) Calculate the historical value-at-risk at the 99% confidence level for a ten-day time horizon.
- (b) Calculate the historical expected shortfall at the 97.5% confidence level for a ten-day time horizon.
- (c) Give an approximation of the capital charge under Basel II, Basel II.5 and Basel III/FRTB Standards by considering the historical risk measure<sup>1</sup>.

## 7 Credit spreads

We consider a CDS 3M with two-year maturity and \$1 mn notional principal. The recovery rate  $\mathcal{R}$  is equal to 40% whereas the spread s is equal to 150 bps at the inception date. We assume that the protection leg is paid at the default time.

- 1. Give the cash flow chart. What is the P&L of the protection seller A if the reference entity does not default? What is the P&L of the protection buyer B if the reference entity defaults in one year and two months?
- 2. What is the relationship between s,  $\mathcal{R}$  and  $\lambda$ ? What is the implied one-year default probability at the inception date?
- 3. Seven months later, the CDS spread has increased and is equal to 450 bps. Estimate the new default probability. The protection buyer B decides to realize his P&L. For that, he reassigns the CDS contract to the counterparty C. Explain the offsetting mechanism if the risky PV01 is equal to 1.189.

# 8 Calculation of the capital charge for counterparty credit risk

We denote by e(t) the potential future exposure of an OTC contract with maturity T. The current date is set to t = 0. Let N and  $\sigma$  be the notional and the volatility of the underlying contract. We assume that  $e(t) = N\sigma\sqrt{t}X$  with  $0 \le X \le 1$ ,  $\Pr\{X \le x\} = x^{\gamma}$  and  $\gamma > 0$ .

1. Calculate the peak exposure  $PE_{\alpha}(t)$ , the expected exposure EE(t) and the effective expected positive exposure EEPE(0; t).

 $<sup>^1\</sup>mathrm{We}$  assume that the multiplicative factor is equal to 3, and the 'stressed' risk measure is 2 times the 'normal' risk measure.

- 2. The bank manages the credit risk with the foundation IRB approach and the counterparty credit risk with an internal model. We consider an OTC contract with the following parameters: N is equal to \$3 mn, the maturity T is one year, the volatility  $\sigma$  is set to 20% and  $\gamma$  is estimated at 2.
  - (a) Calculate the exposure at default EAD knowing that the bank uses the regulatory value for the parameter  $\alpha$ .
  - (b) The default probability of the counterparty is estimated at 1%. Calculate then the capital charge for counterparty credit risk of this OTC contract<sup>2</sup>.

#### 9 Parametric estimation of the loss severity distribution

We assume that the severity losses are log-logistic distributed  $X_i \sim \mathcal{LL}(\alpha, \beta)$  with:

$$\mathbf{F}(x;\alpha,\beta) = \frac{(x/\alpha)^{\beta}}{1 + (x/\alpha)^{\beta}}$$

- 1. Calculate the log-likelihood function of the sample  $\{x_1, \ldots, x_n\}$ .
- 2. Show that the ML estimators satisfy the following first-order conditions:

$$\begin{cases} \sum_{i=1}^{n} \mathbf{F}\left(x_{i}; \hat{\alpha}, \hat{\beta}\right) = n/2\\ \sum_{i=1}^{n} \left(2\mathbf{F}\left(x_{i}; \hat{\alpha}, \hat{\beta}\right) - 1\right) \ln x_{i} = n/\hat{\beta} \end{cases}$$

3. What does the log-likelihood function of the sample  $\{x_1, \ldots, x_n\}$  become if we assume that the losses were collected beyond a threshold H?

#### 10 The bivariate Pareto copula

We consider the bivariate Pareto distribution:

$$\mathbf{F}(x_1, x_2) = 1 - \left(\frac{\theta_1 + x_1}{\theta_1}\right)^{-\alpha} - \left(\frac{\theta_2 + x_2}{\theta_2}\right)^{-\alpha} + \left(\frac{\theta_1 + x_1}{\theta_1} + \frac{\theta_2 + x_2}{\theta_2} - 1\right)^{-\alpha}$$

where  $x_1 \ge 0, x_2 \ge 0, \theta_1 > 0, \theta_2 > 0$  and  $\alpha > 0$ .

- 1. Show that the marginal functions of  $\mathbf{F}(x_1, x_2)$  correspond to univariate Pareto distributions<sup>3</sup>.
- 2. Find the copula function associated to the bivariate Pareto distribution.
- 3. Deduce the copula density function.
- 4. Show that the bivariate Pareto copula function has no lower tail dependence  $(\lambda^{-} = 0)$ , but an upper tail dependence  $(\lambda^{+} = 2^{-\alpha})$ .
- 5. Do you think that the bivariate Pareto copula family can reach the copula functions  $\mathbf{C}^-$ ,  $\mathbf{C}^\perp$  and  $\mathbf{C}^+$ ? Justify your answer.
- 6. Let  $X_1$  and  $X_2$  be two Pareto-distributed random variables, whose parameters are  $(\alpha_1, \theta_1)$  and  $(\alpha_2, \theta_2)$ .

$$\mathbf{F}(x) = 1 - \left(\frac{\theta + x}{\theta}\right)^{-1}$$

where  $x \ge 0, \theta > 0$  and  $\alpha > 0$ .

<sup>&</sup>lt;sup>2</sup>We will take a value of 70% for the LGD parameter and a value of 20% for the default correlation. We remind that  $\Phi^{-1}(0.01) \approx -2.33$  and  $\Phi^{-1}(0.999) \approx 3.09$ . We can also use the approximation  $-1.06 \approx -1$  and  $\Phi(-1) \approx 16\%$ .

<sup>&</sup>lt;sup>3</sup>We remind that the univariate Pareto distribution  $\mathcal{P}(\alpha, \theta)$  can be written as:

- (a) Show that the linear correlation between  $X_1$  and  $X_2$  is equal to 1 if and only if the parameters  $\alpha_1$  and  $\alpha_2$  are equal.
- (b) Show that the linear correlation between  $X_1$  and  $X_2$  can never reached the lower bound -1.
- (c) Build a new bivariate Pareto distribution by assuming that the marginal distributions are  $\mathcal{P}(\alpha_1, \theta_1)$  and  $\mathcal{P}(\alpha_2, \theta_2)$  and the dependence is a bivariate Pareto copula function with parameter  $\alpha$ . What is the relevance of this approach for building bivariate Pareto distributions?

#### 11 Extreme value theory in the bivariate case

- 1. What is an extreme value (EV) copula  $\mathbf{C}$ ?
- 2. Show that  $\mathbf{C}^{\perp}$  and  $\mathbf{C}^{+}$  are EV copulas. Why  $\mathbf{C}^{-}$  cannot be an EV copula?
- 3. We define the Gumbel-Hougaard copula as follows:

$$\mathbf{C}(u_1, u_2) = \exp\left(-\left[(-\ln u_1)^{\theta} + (-\ln u_2)^{\theta}\right]^{1/\theta}\right)$$

with  $\theta \geq 1$ . Verify that it is an EV copula.

- 4. What is the definition of the upper tail dependence  $\lambda$ ? What is its usefulness in multivariate extreme value theory?
- 5. Let f(x) and g(x) be two functions such that  $\lim_{x\to x_0} f(x) = \lim_{x\to x_0} g(x) = 0$ . If  $g'(x_0) \neq 0$ , L'Hospital's rule states that:

$$\lim_{x \to x_0} \frac{f(x)}{g(x)} = \lim_{x \to x_0} \frac{f'(x)}{g'(x)}$$

Deduce that the upper tail dependence  $\lambda$  of the Gumbel-Hougaard copula is  $2 - 2^{1/\theta}$ . What is the correlation of two extremes when  $\theta = 1$ ?
