Some models

Most Popular Models in Asset Allocation

- Mean-variance portfolio selection (Markowitz, 1952) (minimum-variance strategy, tangency portfolio, strategic asset allocation, market-cap indexation, etc.)
- Dynamic optimization (Merton, 1971) (constant-mix strategy, liability-driven investment, lifecycle funds, target date funds, etc.)
- Tactical asset allocation (Black-Litterman, 1992) (equilibrium portfolios, flexible views, market timing, etc.)

 \Rightarrow These 3 models are based on optimization techniques.

 $\mathcal{A} \mathcal{A} \mathcal{A}$

Some Models Robustness of the Markowitz framework Weights constraints and Portfolio Theory

The Markowitz framework

In the portfolio theory of Markowitz, we maximize the expected return for a given level of volatility:

$$\max \mu\left(w
ight)=\mu^ op w$$
 u.c. $\sigma\left(w
ight)=\sqrt{w^ op\Sigma w}=\sigma^\star$

- Optimized portfolios with respect to volatility and expected return
- The optimal portfolio is the tangency portfolio
- Confusion between volatility and diversification concepts
- The solution is not robust; it is highly sensitive to expected return inputs
- High turnover of the portfolio

 $\mathcal{O} \mathcal{Q} \mathcal{O}$

Some Models Robustness of the Markowitz framework Weights constraints and Portfolio Theory

Stability

We consider the minimum-variance portfolio (because it does not depend on expected returns).

2 assets with $\sigma_1(t) = \sigma_2(t) = 20\%$ and $\rho_{1,2}(t) = 100\%$:

 $w_1^{\star}(t) = w_2^{\star}(t) = 50\%$

In t+1, if the volatility of the first $\sigma_1(t+1) = 19,9\%$, we obtain:

$$w_1^{\star}(t+1) = 100\%$$
 and $w_2^{\star}(t+1) = 0\%$

<ロト < 団ト < 団ト < 団ト = 三日

 $\mathcal{O} \mathcal{Q} \mathcal{O}$

Some Models Robustness of the Markowitz framework Weights constraints and Portfolio Theory

An example

3 assets with $\sigma_1(t) = 20\%$, $\sigma_2(t) = 22\%$ and $\sigma_3(t) = 23\%$ and a uniform correlation ρ . We assume that the true correlation ρ is 90%.

Table: Optimal portfolios

				Estimated	correlation				
		Ν	No short sellin	g	With short selling				
Asset	EW	90%	85%	95%	90%	85%	95%		
1	33.33%	95.65%	70.09%	100.00%	100.00%	70.09%	100.00%		
2	33.33%	4.35%	23.78%	0.00%	17.61%	23.78%	36.82%		
3	33.33%	0.00%	6.13%	0.00%	-17.61%	6.13%	-36.82%		
Volatility	20.93%	20.00%	20.17%	20.00%	19.92%	20.17%	20.02%

The Markowitz Optimization Enigma: Is "Optimized" Optimal?

JQ (~

Some Models Robustness of the Markowitz framework Weights constraints and Portfolio Theory

On the importance of the information matrix

Let μ and Σ be the vector of expected returns and the covariance matrix. Optimal solutions are of the following form:

$$w^{\star} \propto \Sigma^{-1} \mu$$

In the case of the minimum-variance portfolio, the form is:

$$w^{\star} \propto \Sigma^{-1} \mathbf{1}$$

The important quantity is $\mathscr{I} = \Sigma^{-1}$, which is called the information matrix.

<ロト < 同ト < ヨト < ヨト -

Some Models Robustness of the Markowitz framework Weights constraints and Portfolio Theory

Which factors are important?

Eigendecomposition of the information matrix

The eigendecomposition of $\mathscr{I} = \Sigma^{-1}$ is the same as the one of Σ , but with reverse order of eigenvectors and inverse eigenvalues:

$$egin{array}{rcl} V_i(\mathscr{I}) &=& V_{n-i}(\Sigma) \ \lambda_i(\mathscr{I}) &=& rac{1}{\lambda_{n-i}(\Sigma)} \end{array}$$

Table: Example with the previous covariance matrix (with correlation 90%)

	Co	ovariance mat	rix	Information matrix				
Asset / Factor	1	2 3		1	2	3		
1	52.88%	-13.02%	83.87%	83.87%	-13.02%	52.88%		
2	58.56%	-65.93%	-47.16%	-47.16%	-65.93%	58.56%		
3	61.44%	74.05%	-27.25%	-27.25%	74.05%	61.44%		
Eigenvalues	0.1319	0.0051	0.0043	233.4190	197.1199	7.5790		
% cumulated	93.4%	97.0%	100.0%	53.3%	98.3%	100.0%		

▲□▶▲□▶▲□▶▲□▶ ▲□

Solutions

Because the optimal solution depends principally on the last factors of the covariance matrix, we have to introduce some regularization techniques:

- regularization of the objective function by using resampling techniques
- regularization of the covariance matrix:
 - Factor analysis
 - Shrinkage methods
 - Random matrix theory
 - etc.
- regularization of the program specification by introducing some constraints

Some Models Robustness of the Markowitz framework Weights constraints and Portfolio Theory

Main result

We consider a universe of *n* assets. We denote by μ the vector of their expected returns and by Σ the corresponding covariance matrix. We specify the optimization problem as follows:

$$\min \frac{1}{2} w^{\top} \Sigma w$$

u.c.
$$\begin{cases} \mathbf{1}^{\top} w = 1\\ \mu^{\top} w \ge \mu^{\star}\\ w \in \mathbb{R}^{n} \cap \mathscr{C} \end{cases}$$

where w is the vector of weights in the portfolio and \mathscr{C} is the set of weights constraints. We define:

• the unconstrained portfolio w^* or $w^*(\mu, \Sigma)$:

$$\mathscr{C} = \mathbb{R}^n$$

• the constrained portfolio \tilde{w} :

$$\mathscr{C}(w^{-},w^{+}) = \left\{ w \in \mathbb{R}^{n} : w_{i}^{-} \leq w_{i} \leq w_{i}^{+} \right\}$$

Theorem

Jagannathan and Ma (2003) show that the constrained portfolio is the solution of the unconstrained problem:

$$ilde{w} = w^{\star}\left(ilde{\mu}, ilde{\Sigma}
ight)$$

with:

$$\left\{ egin{array}{l} ilde{\mu} & \ ilde{\Sigma} = \Sigma + (\lambda^+ - \lambda^-) \, \mathbf{1}^ op + \mathbf{1} \left(\lambda^+ - \lambda^-
ight)^ op \end{array}
ight.$$

where λ^- and λ^+ are the Lagrange coefficients vectors associated to the lower and upper bounds.

 \Rightarrow Introducing weights constraints is equivalent to introduce some relative views (similar to the **Black-Litterman** approach).

Some Models Robustness of the Markowitz framework Weights constraints and Portfolio Theory

Proof for the global minimum-variance portfolio

We define the Lagrange function as $f(w; \lambda_0) = \frac{1}{2}w^{\top}\Sigma w - \lambda_0 (\mathbf{1}^{\top}w - 1)$ with $\lambda_0 \ge 0$. The first order conditions are $\Sigma w - \lambda_0 \mathbf{1} = 0$ and $\mathbf{1}^{\top}w - 1 = 0$. We deduce that the optimal solution is:

$$w^{\star} = \lambda_0^{\star} \Sigma^{-1} \mathbf{1} = \frac{1}{\mathbf{1}^{\top} \Sigma \mathbf{1}} \Sigma^{-1} \mathbf{1}$$

With weights constraints $\mathscr{C}(w^-, w^+)$, we have:

$$f(w;\lambda_0,\lambda^-,\lambda^+) = \frac{1}{2}w^{\top}\Sigma w - \lambda_0 \left(\mathbf{1}^{\top}w - \mathbf{1}\right) - \lambda^{-\top} \left(w - w^{-}\right) - \lambda^{+\top} \left(w^+ - w\right)$$

with $\lambda_0 \ge 0$, $\lambda_i^- \ge 0$ and $\lambda_i^+ \ge 0$. In this case, the first-order conditions becomes $\Sigma w - \lambda_0 \mathbf{1} - \lambda^- + \lambda^+ = 0$ and $\mathbf{1}^\top w - 1 = 0$. We have:

$$\tilde{\Sigma}\tilde{w} = \left(\Sigma + \left(\lambda^{+} - \lambda^{-}\right)\mathbf{1}^{\top} + \mathbf{1}\left(\lambda^{+} - \lambda^{-}\right)^{\top}\right)\tilde{w} = \left(2\tilde{\lambda}_{0} - \tilde{w}^{\top}\Sigma\tilde{w}\right)\mathbf{1}$$

Because $\tilde{\Sigma}\tilde{w}$ is a constant vector, it proves that \tilde{w} is the solution of the unconstrained optimisation problem with $\lambda_0^{\star} = \left(2\tilde{\lambda}_0 - \tilde{w}^\top \Sigma \tilde{w}\right)$.

Some Models Robustness of the Markowitz framework Weights constraints and Portfolio Theory

Examples

Table: Specification of the covariance matrix Σ (in %)

σ_i	$ ho_{i,j}$											
15.00	100.00											
20.00	10.00	100.00										
25.00	40.00	70.00	100.00									
30.00	50.00	40.00	80.00	100.00								

Given these parameters, the global minimum variance portfolio is equal to:

$$w^{\star} = \left(\begin{array}{c} 72.742\% \\ 49.464\% \\ -20.454\% \\ -1.753\% \end{array}\right)$$

Ξ.

Risk-budgeting principles The ERC portfolio

Euler decomposition of risk measures

Let $\mathscr{R}(w_1, \ldots, w_n)$ be a coherent convex risk measure. We have:

$$\mathscr{R}(w_1,\ldots,w_n) = \sum_{i=1}^n \underbrace{w_i \cdot \frac{\partial \mathscr{R}(w_1,\ldots,w_n)}{\partial w_i}}_{RC_i}$$

 RC_i is the risk contribution of the i^{th} asset: it is the product of its weight by its marginal risk.

Let us consider a set of **given** risk budgets $\{RB_1, \ldots, RB_n\}$, the risk-budgeted portfolio is defined by:

$$RC_{1}(w_{1},...,w_{n}) = RB_{1}$$

$$RC_{i}(w_{1},...,w_{n}) = RB_{i}$$

$$RC_{n}(w_{1},...,w_{n}) = RB_{n}$$

< = > < = >

Risk-budgeting principles The ERC portfolio

When the risk measure is the volatility of the portfolio

Let Σ and w be the covariance matrix and the portfolio weights. We have:

$$\mathscr{R}(w) = \sigma(w) = \sqrt{w^{\top} \Sigma w}$$

We deduce that:

$$\frac{\partial \mathscr{R}(w)}{\partial w} = \frac{\Sigma w}{\sqrt{w^{\top} \Sigma w}}$$

The risk contribution of the i^{th} asset is then:

$$RC_i = w_i \cdot \frac{(\Sigma w)_i}{\sqrt{w^\top \Sigma w}}$$

We verify that this risk measure is convex:

$$\sum_{i=1}^{n} RC_{i} = \sum_{i=1}^{n} w_{i} \cdot \frac{(\Sigma w)_{i}}{\sqrt{w^{\top} \Sigma w}} = w^{\top} \frac{\Sigma w}{\sqrt{w^{\top} \Sigma w}} = \sqrt{w^{\top} \Sigma w} = \mathscr{R}(w)$$

JQ (~

Illustration

- 3 assets
- Volatilities are respectively 20%, 30% and 15%
- Correlations are set to 60% between the 1st asset and the 2nd asset and 10% between the first two assets and the 3rd asset

The marginal risk for the first asset is:

$$\lim_{\varepsilon \to 0} \frac{\sigma(w_1 + \varepsilon, w_2, w_3) - \sigma(w_1, w_2, w_3)}{(w_1 + \varepsilon) - w_1}$$

If
$$\varepsilon = 1\%$$
, we have:
 $rac{\partial \mathscr{R}(x)}{\partial w_1} \simeq rac{16.72\% - 16.54\%}{1\%} = 18.01\%$

Traditional approach

2	49.31%	9.35%	4.61%	33.33%		
Volatility			13.82%			

Definition

The Euler decomposition gives us:

$$\sigma(w) = \sum_{i=1}^{n} w_i \times \frac{\partial \sigma(w)}{\partial w_i} = \sum_{i=1}^{n} \mathrm{RC}_i$$

The ERC portfolio is the risk-balanced portfolio such that the risk contribution is the same for all assets of the portfolio:

$$RC_i = RC_j$$
 for all i, j

The ERC portfolio is then the solution of the following non-linear system:

$$\begin{cases} w_2 \times (\Sigma w)_2 = w_1 \times (\Sigma w)_1 \\ w_3 \times (\Sigma w)_3 = w_1 \times (\Sigma w)_1 \\ \vdots \\ w_n \times (\Sigma w)_n = w_1 \times (\Sigma w)_1 \\ w_1 + w_2 + \dots + w_n = 1 \\ w_1 > 0, w_2 > 0, \dots, w_n > 0 \end{cases}$$

< = > < = >

э.

 $\mathcal{O} \mathcal{Q} \mathcal{O}$

Risk-budgeting principles The ERC portfolio

Properties

Consider the following optimization problem:

$$w^{\star}(c) = rgmin \sqrt{w^{\top} \Sigma w}$$

u.c. $\begin{cases} \sum_{i=1}^{n} \ln w_i \ge c \\ \mathbf{1}^{\top} w = 1 \\ \mathbf{0} \le w \le \mathbf{1} \end{cases}$

We have $w^*(-\infty) = w_{mv}$ and $w^*(-n \ln n) = w_{1/n}$. The ERC portfolio corresponds to a particular value of c such that $-\infty \le c \le -n \ln n$.

- The solution of the ERC problem exists and is **unique**.
- **2** We also obtain the following inequality:

$$\sigma_{mv} \leq \sigma_{erc} \leq \sigma_{1/n}$$

because if $c_1 \leq c_2$, we have $\sigma(w^*(c_1)) \leq \sigma(w^*(c_2))$. The ERC portfolio may be viewed as a portfolio "between" the 1/n portfolio and the minimum-variance portfolio.

The ERC portfolio is a form of variance-minimizing portfolio subject to a constraint of sufficient diversification in terms of weights.

• If the correlations are the same, the solution is:

$$w_i = \frac{\sigma_i^{-1}}{\sum_{j=1}^n \sigma_j^{-1}}$$

The weight allocated to each component *i* is given by the ratio of the inverse of its volatility with the harmonic average of the volatilities.

• If the volatilities are the same, we have:

$$w_i \propto \left(\sum_{k=1}^n w_k \rho_{ik}\right)^{-1}$$

The weight of the asset *i* is proportional to the inverse of the weighted average of correlations of component *i* with other components.

• In the general case, we obtain:

$$w_i \propto \beta_i^{-1}$$

The weight of the asset *i* is proportional to the inverse of its beta.

- The ERC portfolio is the tangency portfolio if all the assets have the same Sharpe ratio and if the correlation is uniform (one-factor model).
- Let us consider the minimum variance portfolio with a constant correlation matrix $C_n(\rho)$. The solution is:

$$w_{i} = \frac{-((n-1)\rho+1)\sigma_{i}^{-2} + \rho\sum_{j=1}^{n}(\sigma_{i}\sigma_{j})^{-1}}{\sum_{k=1}^{n}(-((n-1)\rho+1)\sigma_{k}^{-2} + \rho\sum_{j=1}^{n}(\sigma_{k}\sigma_{j})^{-1})}$$

The lower bound of $C_n(\rho)$ is achieved for $\rho = -(n-1)^{-1}$ and we have:

$$w_i = \frac{\sum_{j=1}^n (\sigma_i \sigma_j)^{-1}}{\sum_{k=1}^n \sum_{j=1}^n (\sigma_k \sigma_j)^{-1}} = \frac{\sigma_i^{-1}}{\sum_{k=1}^n \sigma_k^{-1}} \to \text{erc}$$

• The ERC portfolio minimizes the Gini and Herfindal indexes applied to the risk measure.

Pros and cons of market-cap indexation

Pros of market-cap indexation

- A convenient and **recognized approach** to participate to broad equity markets.
- Management simplicity: low turnover & transaction costs.

Cons of market-cap indexation

- Trend-following strategy: momentum bias leads to bubble risk exposure as weight of best performers ever increases.
 - \Rightarrow Mid 2007, financial stocks represent 40% of the Eurostoxx 50 index.
- Growth biais as high valuation multiples stocks weight more than low-multiple stocks with equivalent realised earnings.

 \Rightarrow Mid 2000, the 8 stocks of the technology/telecom sectors represent 35% of the Eurostoxx 50 index.

- \Rightarrow 2¹/₂ years later after the dot.com bubble, these two sectors represent 12%.
- Concentrated portfolios.
 - \Rightarrow The top 100 market caps of the S&P 500 account for around 70%.
- Lack of risk diversification and high drawdown risk: no portfolio construction rules leads to concentration issues (e.g. sectors, stocks).

▲□ ▶ ▲ □ ▶ ▲ □ ▶

Alternative-weighted indexation

Alternative-weighted indexation aims at building passive indexes where the weights are not based on market capitalization.

Two sets of responses:

- Fundamental indexation \Rightarrow promising alpha
 - Dividend yield indexation
 - **2** RAFI indexation
- **2** Risk-based indexation \Rightarrow promising diversification
 - Equally weighted (1/n)
 - O Minimum-variance portfolio
 - **3** ERC portfolio
 - MDP/MSR portfolio

□ ▶ ▲ ■ ▶ ▲ ■ ▶ →

3

Risk-based indexation Risk parity funds Bond portfolios management

Risk-based methods

Equally-weighted (1/n)

- Weights are equal
- Easy to understand
- Contrarian strategy with a take-profit scheme
- The least concentrated in terms of weights
- Do not depend on risks

Most Diversified Portfolio (MDP)

- Also known as the Max Sharpe Ratio (MSR) portfolio of EDHEC
- Based on the assumption that sharpe ratio is equal for all stocks
- It is the tangency portfolio if the previous assumption is verified
- Sensitive to the covariance matrix

Minimum-variance (MV)

- Low volatility portfolio
- The only optimal portfolio not depending on expected returns assumptions
- Good out of sample performance
- Concentrated portfolios
- Sensitive to the covariance matrix

Equal-Risk Contribution (ERC)

- Risk contributions are equal
- Highly diversified portfolios
- Less sensitive to the covariance matrix (than the MV and MDP portfolios)
- Not efficient for universe with a large number of stocks (equivalent to the 1/n portfolio)

 $Q (\sim$

Risk-based indexation Risk parity funds Bond portfolios management

Comparison of the 4 Methods

In terms of bets

$$\exists i : w_i = 0 \quad (\mathsf{MV} - \mathsf{MDP}) \\ \forall i : w_i \neq 0 \quad (1/\mathsf{n} - \mathsf{ERC})$$

In terms of risk factors

$$W_{i} = W_{j} \qquad (1/n)$$

$$\frac{\partial \sigma(w)}{\partial w_{i}} = \frac{\partial \sigma(w)}{\partial w_{j}} \qquad (MV)$$

$$W_{i} \times \frac{\partial \sigma(w)}{\partial w_{i}} = W_{j} \times \frac{\partial \sigma(w)}{\partial w_{j}} \qquad (ERC)$$

$$\frac{1}{\sigma_{i}} \times \frac{\partial \sigma(w)}{\partial w_{i}} = \frac{1}{\sigma_{j}} \times \frac{\partial \sigma(w)}{\partial w_{j}} \qquad (MDP)$$

Risk-based indexation Risk parity funds Bond portfolios management

Application to the Eurostoxx 50 index

Figure: Performance of the ERC Eurozone Index (Ticker: SGIXERCE Index)

Justification of diversified funds

Investor Profiles

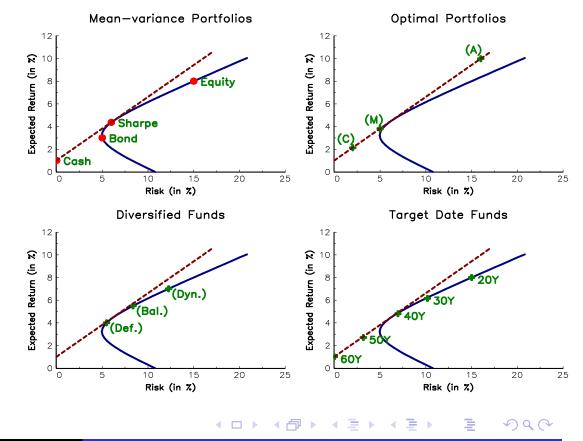

- Moderate (medium risk tolerance)
- Conservative (low risk tolerance)
- Aggressive (high risk tolerance)

Fund Profiles

- Defensive (80% bonds and 20% equities)
- Balanced (50% bonds and 50% equities)
- Oynamic (20% bonds and 80% equities)

Relationship with portfolio theory?

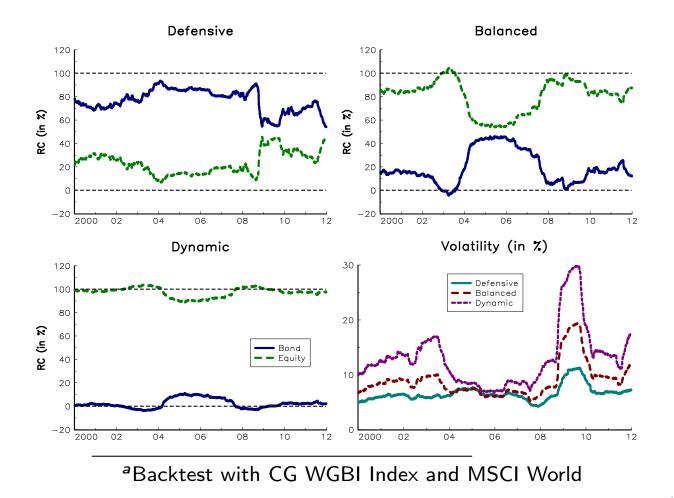

Figure: The asset allocation puzzle

Risk-based indexation Risk parity funds Bond portfolios management

What type of diversification offer diversified funds?

Figure: Risk contribution of diversified funds^a

Diversified funds = Marketing idea?

- Deleverage of an equity exposure
- Diversification in weights \neq Risk diversification
- No mapping between fund profiles and volatility profiles
- No mapping between fund profiles and investor profiles

∍

 $\mathcal{O} \mathcal{Q} \mathcal{O}$

ERC diversified funds

Risk-based indexation Risk parity funds Bond portfolios management

Risk parity funds

Definition

A risk parity fund is an ERC startegy on multi-assets classes.

Some examples

- AQR Capital Management
- Bridgewater
- Invesco
- Lyxor Asset Management
- PanAgora Asset Management
- Wegelin Asset Management

Statistical measures of concentration

- The Lorenz curve L(x)
 It is a graphical representation of the concentration. It represents the cumulative weight of the first x% most representative stocks.
- The Gini coefficient It is a dispersion measure based on the Lorenz curve:

$$G = \frac{A}{A+B} = 2\int_0^1 \mathscr{L}(x) \, \mathrm{d}x - 1$$

G takes the value 1 for a perfectly concentrated portfolio and 0 for the equally-weighted portfolio.

• The risk concentration of a portfolio is analyzed using Lorenz curve and Gini coefficient applied to risk contributions.

 \Rightarrow High turnover of min- and mean-variance portfolios (stability issue)

 \Rightarrow ERC = risk-balanced dynamic allocation with moderate turnover \blacksquare

Risk-based indexation Risk parity funds Bond portfolios management

Bond portfolios management

- Cap-weighted indexation for equities \Rightarrow debt-weighted indexation for bonds
- In Fund management driven by the search of yield
- \Rightarrow Time to rethink bond indexes? (Toloui, 2010)

590

Risk-based indexation Risk parity funds Bond portfolios management

Bond portfolios management

Debt weighting It is defined by^a:

 $w_i = \frac{\text{DEBT}_i}{\sum_{i=1}^n \text{DEBT}_i}$

^aTwo forms of debt-weighting are considered : DEBT (with the 11 countries) and DEBT* (without Greece after July 2010). This last one corresponds to the weighting scheme of the EGBI index.

Alternative weighting

Eundamental indexation The GDP-weighting is defined by:

$$w_i = \frac{\text{GDP}_i}{\sum_{i=1}^n \text{GDP}_i}$$

Q Risk-based indexation The DEBT-RB and GDP-RB weightings are defined by:

$$RB_{i} = \frac{DEBT_{i}}{\sum_{i=1}^{n} DEBT_{i}}$$
$$RB_{i} = \frac{GDP_{i}}{\sum_{i=1}^{n} GDP_{i}}$$

3

Choosing the right measure of credit risk

- Volatility of price returns \neq a good measure of credit risk
- Correlation of price returns \neq a good measure of contagion
- A better measure is the yield spread, but it is difficult to compute because it is difficult to define the reference (risk-free) rate.

 \Rightarrow One of the best measure is the CDS spread (it does not depend on the currency, the yield curve or the duration).

The CDS model

Let $S_i(t)$ be the spread of the *i*th issuer. We have:

$$\mathrm{d}S_{i}(t) = \sigma_{i}^{S} \cdot S_{i}(t) \cdot \mathrm{d}W_{i}(t)$$

Moreover, we assume that the correlation between the brownian motions $W_i(t)$ and $W_j(t)$ is $\Gamma_{i,j}$.

Computing the credit risk measure of a bond portfolio

Let $w = (w_1, ..., w_n)$ be the weights of bonds in the portfolio. The risk measure is:

$$\mathscr{R}(x) = \sqrt{w^{\top} \Sigma w} = \sqrt{\sum_{i=1}^{n} \sum_{j=1}^{n} w_i w_j \Sigma_{i,j}}$$

with $\Sigma_{i,j} = \Gamma_{i,j} \cdot \sigma_i^B \cdot \sigma_j^B$ and $\sigma_i^B = D_i \cdot \sigma_i^S \cdot S_i(t)$, where D_i is the duration of the bond *i*, σ_i^S is the CDS volatility of the corresponding issuer, $S_i(t)$ is the CDS level and $\Gamma_{i,j}$ is the correlation between the CDS relative variations of issuers corresponding to the bonds *i* and *j*.

 $\mathscr{R}(w)$ is the volatility of the CDS basket which would perfectly hedge the credit risk of the bond portfolio.

 $\mathscr{R}(w)$ depends on 3 "CDS" parameters $S_i(t)$, σ_i^S and $\Gamma_{i,j}$ and two "portfolio" parameters w_i and D_i .

Statistics as of December 1st, 2011

Table: CDS levels $S_i(t)$, volatilities σ_i^S and correlations $\Gamma_{i,j}$

Country	Spread	Vol.	AT	BE	FI	FR	DE	GR	IE	IT	NL	РТ	ES

Netherlands	105	65.1%	78%	76%	76%	78%	83%	32%	64%	71%	100%		
Portugal	1,048	55.3%	60%	73%	52%	62%	59%	44%	82%	75%	58%	100%	
Spain	390	70.6%	72%	79%	60%	69%	65%	32%	71%	80%	64%	70%	100%

Defining the risk contribution

Our credit risk measure $\mathscr{R}(w) = \sqrt{w^{\top}\Sigma w}$ is a convex risk measure. It means that:

$$\mathscr{R}(w_1,\ldots,w_n) = \sum_{i=1}^n w_i \cdot \frac{\partial \mathscr{R}(w_1,\ldots,w_m)}{\partial w_i}$$
$$= \sum_{i=1}^n RC_i$$

We can then decompose the risk measure exactly by n individual sources of risk.

The risk contribution RC_i is an increasing function of the parameters D_i , $S_i(t)$ and σ_i^S .

- 218 funds

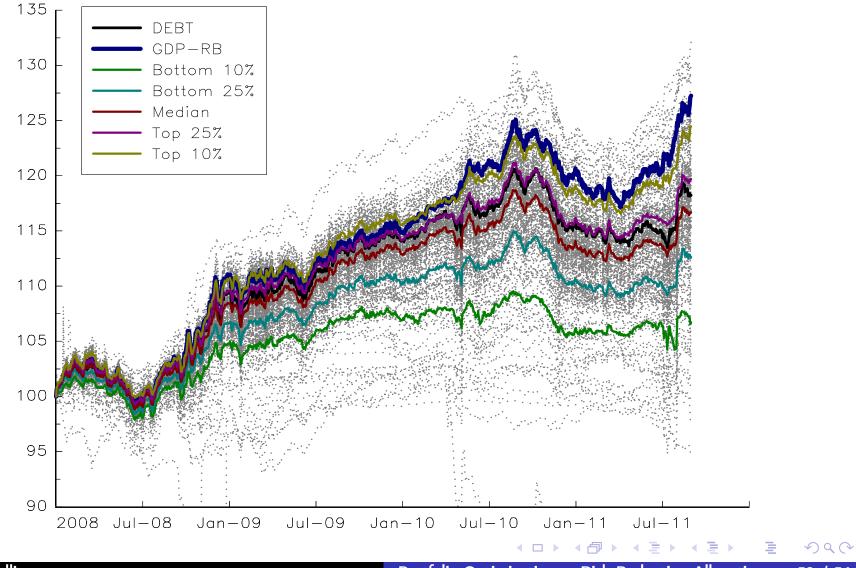

The Academic Rule³:

Average Performance of Active Management = Performance of the Index – Management Fees

 \Rightarrow Implied fees for Bond EURO Government: 36 bps / year

Risk-based indexation Risk parity funds Bond portfolios management

Comparison with active management

Conclusion

- Portfolio optimization leads to concentrated portfolios in terms of weights and risk
- The use of weights constraints to diversify is equivalent to a discretionary shrinkage method
- Risk-budgeting techniques is a better approach to diversify portfolios
- Strong focus on ERC portfolios last years from the asset management industry (equity indexes, risk parity funds, commodity funds, multi-strategy funds)
